

Node-level optimization

Remove Identity

Before
 $y = \text{identity}(x)$

After
 $y = x$

Remove zero padding

Before
 $y = \text{pad}(x, \text{padding}=(0, 0, 0, 0))$

After
 $y = x$

DataFlow-level optimization

Common subexpression elimination

Before
 $u = a + b$
 $v = a + b$
 $y = u * v$

After
 $u = a + b$
 $y = u * v$

Static memory planning

Before: each intermediate gets a separate buffer
 $\text{Buf1} = \text{conv2d}(x, w1)$
 $\text{Buf2} = \text{relu}(\text{buf1})$
 $\text{Buf3} = \text{conv2d}(\text{buf2}, w2)$

After: buffers with non-overlapping lifetimes can be reused
 $\text{bufA} = \text{conv2d}(x, w1)$
 $\text{bufB} = \text{relu}(\text{bufA})$
 $\text{bufA} = \text{conv2d}(\text{bufB}, w2)$
bufA reused after its previous value is dead

Block-level optimization

Constant Folding

Before
 $\text{scale} = 2.0 * 3.0$
 $y = x * \text{scale}$

After
 $y = x * 6.0$

Strength reduction

Before
 $y = x * 8$

After
 $y = x \ll 3$

Operator sinking

Before
 $x \rightarrow \text{Transpose} \rightarrow \text{ReLU} \rightarrow \text{Transpose}^{\{-1\}} \rightarrow y$

After
 $x \rightarrow \text{ReLU} \rightarrow \text{Transpose} \rightarrow \text{Transpose}^{\{-1\}} \rightarrow y$

Operation fusion

conv

BiasAdd

ReLU

Fused
Conv + Bias + ReLU
